(Dated: August, 2004)

Abstract

A minimal SO(10) model with $\mathbf{126}$ Higgs field breaking B-L symmetry has been shown recently to predict large solar and atmospheric mixings in agreement with observations if it is assumed that the neutrino mass follows from the triplet dominated type II seesaw formula. No additional symmetries need to be assumed for this purpose. We discuss the conditions on the way SO(10) symmetry breaks down to MSSM and the Higgs multiplets in the model, required for the triplet dominated type II seesaw formula to hold. We find that (i) SO(10) must break to a nonminimal SU(5) before breaking to the standard model; (ii) $B − L$ symmetry must break at the time of SO(10) breaking and (iii) constraints of unification seem to require that the minimal model must have a $\mathbf{54}$ dimensional Higgs field together with a $\mathbf{210}$ and $\mathbf{126}$ to break the GUT symmetry.
I. INTRODUCTION

The observed pattern of neutrino masses and mixings have posed a major challenge for particle theory. While the seesaw mechanism is emerging as a compelling way to understand why neutrino masses are so small compared to charged lepton and quark masses, there is no single accepted mechanism to understand large mixings\(^1\). In theories without quark-lepton unification, the large mixings may be a signal of new leptonic symmetries such as $L_e - L_\mu - L_\tau$ for inverted hierarchy or a $\mu \leftrightarrow \tau$ discrete symmetry for normal hierarchy. However, these symmetries cannot be imposed on theories that unify quarks and leptons since there is no trace of them in quark masses and mixings. Therefore understanding large mixing angles in the context of grand unified becomes specially acute. Since grand unified theories (GUT) have a number of interesting features including the fact that the seesaw scale is very close to the GUT scale, it is important to explore ways to understand the large neutrino mixings in the GUT theories.

For neutrino masses, the most interesting grand unification models are those based on the gauge group SO(10)\(^2\) since (i) the $16$ dimensional spinor representation of the group that fits in matter of one generation also contains the right handed neutrino that is an essential part of the seesaw mechanism; (ii) the seesaw mass scale for the right handed neutrino which is determined by the atmospheric neutrino data to be close to the GUT scale receives a natural explanation as the GUT symmetry breaking scale and (iii) SO(10) contains the Pati-Salam subgroup which helps to connect the quark and lepton parameters thereby making the theory potentially more predictive.

While these make the SO(10) models appealing for neutrino mass studies, detailed quantitative predictions often require extra symmetry assumptions beyond SO(10). One exception to this is the class of models that use only one $10$ and one $126$ Higgs multiplet to generate fermion masses\(^3, 4, 5\). In this case, if we ignore CP phases\(^6\), there are only 11 parameters describing the charged fermion masses and mixings. Furthermore, the right handed neutrino mass matrix which ordinarily depends on a new set of parameters, is now given by a subset of the above 11 parameters plus an overall scale. This is a sizable reduction in the number of parameters compared to the standard model extended to include the seesaw mechanism, where we have 31 parameters (30 in the absence of CP violation).

If we further assume that in the type II seesaw formula\(^7\) for neutrino masses that appears
naturally in these models, the triplet term dominates, then the solar mass difference square and the two large mixing angles $\theta_{12}, \theta_{23}$ are predicted and found to be consistent with present observations at 2.5 to 3 $\sigma$ level and $\theta_{13}$ is predicted to be 0.18 which is slightly below the present CHOOZ-Palo-Verde upper limit. The last prediction makes the model testable in the next generation neutrino experiments.

Crucial to the success of the model is the assumption that the triplet term in the type II seesaw formula dominates over the second term. In this paper we discuss the conditions under which this happens. We find that they impose nontrivial constraints on the way SO(10) symmetry breaks down to the minimal supersymmetric standard model (MSSM). In particular, we find that SO(10) must break to the standard model via a nonminimal SU(5) model. Secondly, the minimal SO(10) model with the Higgs structure $10, 126 \oplus 126$ and a $210 \up{10} \up{11}$ needs to be extended by the addition of a 54 multiplet.

This paper is divided as follows: in sec. 2, we show that if the triplet term in the type II seesaw mass formula for neutrinos is to dominate, the simplest way is to let SO(10) break to the standard model via a nonminimal SU(5); in sec. 3, we discuss SO(10) breaking via nonminimal SU(5) and discuss the spectrum of SU(5) representations; in sec. 4, we point out that the model requires the the Higgs system to contain a 54 dimensional field in addition to the $210, 10$ and a $126$ pair to allow a light 15-Higgs field; in sec. 5, we provide a detailed analysis of symmetry breaking in the SO(10) model with 54; in sec. 6, we consider gauge coupling unification and determine the values of the SU(5) and the SO(10) scales; sec. 7 gives the conclusions of our study.

II. TYPE II SEESAW FORMULA AND SO(10) SYMMETRY BREAKING

It has been emphasized[7] that in theories that conserve parity asymptotically e.g left-right symmetric and SO(10) models, the seesaw formula takes the form:

$$M_{\nu} \approx f \frac{v_{uk}^2}{M_T} - \frac{m_D^2}{fv_{B-L}}.$$  \hspace{1cm} (1)

where $M_T \simeq \lambda v_{B-L}$, the mass of the triplet Higgs field and the second term represents the formula for models that do not have parity symmetry. This is called the type II seesaw formula. Note that both the terms are inversely proportional to the scale $v_{B-L}$. If in the above formula, the first term is assumed to dominate, then in the minimal SO(10) models
with only one $\mathbf{126}$-Higgs (and arbitrary number of $\mathbf{10}$’s), one obtains a sumrule of the form

$$M_\nu = c(M_d - M_\ell)$$

In the context of minimal SO(10) models with only one $\mathbf{10}$ and one $\mathbf{126}$, this formula provides a very novel mechanism to understand large neutrino mixings as was first pointed out in Ref.\cite{4} for the case of second and third generation neutrinos. The reason for large mixings is the known convergence of the $b$ and $\tau$ masses at the GUT scale which for the case second and third generations leads to large atmospheric neutrino mixing angles without further assumptions\cite{4}. It was not clear at this stage, whether the same mechanism works for the realistic three generation SO(10) models. This was subsequently shown in Ref.\cite{5} that indeed the same $b - \tau$ mass convergence can also explain large solar mixing angle and give a small $\theta_{13}$.

As noted before, all these interesting results of minimal SO(10) are two assumptions: (i) breaking of B-L symmetry by a single $\mathbf{126}$ and (ii) dominance of the triplet induced term in the type II seesaw for neutrino masses. While qualitative arguments have been given in favor of the second assumption, a detailed investigation of this has not been presented to date. In this paper we fill this gap and critically analyze the second assumption using the full Higgs structure of the model.

To see that this is a nontrivial question, first note that which term in Eq.\ref{eq:1} dominates depends on the value of $f_{ij}$ (since the two terms depend on it in different ways). We therefore need the value of the Yukawa couplings $f_{ij}$. Let us first introduce the Yukawa couplings of the model. If we denote the $\mathbf{10}$ Higgs field by $H$, $\mathbf{210}$ by $\Phi$, $\mathbf{126}$ by $\Sigma$ (and the $\mathbf{16}$ spinor by $\psi$, then the matter part of the superpotential consists only of two terms:

$$W = h_{ij} \psi_i \psi_j H + f_{ij} \psi_i \psi_j \Sigma$$

At the GUT scale, this model has eight Higgs doublets (four up type and four down type). By an appropriate doublet-triplet splitting mechanism these four pairs are assumed to reduce to a single MSSM Higgs pair $(\phi_u, \phi_d)$:

$$\begin{align*}
\phi_u &= \alpha_u^u H_5 + \alpha_u^5 \Sigma_5 + \alpha_u^\Phi_5 + \alpha_u^\Sigma_4 \\
\phi_d &= \alpha_d^d H_5 + \alpha_d^\Sigma_5 + \alpha_d^\Phi_5 + \alpha_d^\Sigma_4
\end{align*}$$

4
with the unitary condition $\sum_i |\alpha_i^{u,d}|^2 = 1$. As in the case of MSSM, we will assume that the Higgs doublets $\phi_{u,d}$ have the vevs $<\phi_u^0> = v \sin \beta$ and $<\phi_d^0> = v \cos \beta$, which then leads us to the mass formulae for quarks and leptons.

$$
M_u = \bar{h} + \bar{f}
$$

(5)

$$
M_d = \bar{hr}_1 + \bar{fr}_2
$$

$$
M_e = \bar{hr}_1 - 3r_2\bar{f}
$$

$$
M_{\nu_D} = \bar{h} - 3\bar{f}
$$

where

$$
\bar{h} = 2hv\alpha_1^u \sin \beta
$$

(6)

$$
\bar{f} = \frac{1}{\sqrt{6}}f hv\alpha_2^u \sin \beta
$$

$$
r_1 = \frac{\alpha_1^d}{\alpha_1^u} \cot \beta
$$

$$
r_2 = -\frac{2\alpha_2^d}{\sqrt{3}\alpha_2^u} \cot \beta
$$

As a typical order of magnitude of the couplings $\bar{f}, \bar{h}$, we consider the work in Ref.[5] and choose the values of $r_{1,2}$ determined by the quark masses and mixings and the masses of the charged leptons and find for our choice of parameters[5]

$$
\begin{pmatrix}
3.26 \times 10^{-6} & 1.50 \times 10^{-4} & 5.51 \times 10^{-3} \\
1.50 \times 10^{-4} & -2.40 \times 10^{-4} & -0.0178 \\
5.51 \times 10^{-3} & -0.0178 & 0.473
\end{pmatrix}
$$

(7)

and

$$
\begin{pmatrix}
-7.04 \times 10^{-5} & -2.05 \times 10^{-5} & -7.53 \times 10^{-4} \\
-2.05 \times 10^{-5} & -1.85 \times 10^{-3} & 2.43 \times 10^{-3} \\
-7.53 \times 10^{-4} & 2.43 \times 10^{-3} & -1.64 \times 10^{-3}
\end{pmatrix}
$$

(8)

To get an idea of what kind of requirements are imposed by type II seesaw, note that the largest element in the matrix $f$ is $\sim 10^{-3}$ whereas as that in $h$ is about 0.5. From this we estimate that the biggest contribution to neutrino mass from the second term (the canonical seesaw term) is about $\sim \frac{m_i^2(M_U)}{v_{B-L}^{ij}} \simeq 3 \times 10^6 GeV$. For $v_{B-L} \simeq M_U \simeq 2 \times 10^{16}$ GeV, this gives an estimate for $\sqrt{\Delta m_A^2} \simeq 0.15 eV$ which is slightly bigger than the experimental value. If type II seesaw is to hold this must be much smaller than $\sqrt{\Delta m_A^2} \simeq 0.05 eV$. If we take
this number to be 0.02 eV, it would require a value of $v_{B-L} \simeq 10^{17}$ GeV. Furthermore, for the first term to give the correct value for $\sqrt{\Delta m^2_{A}}$, the mass of of the color singlet, $SU(2)_L$ triplet Higgs field (denoted henceforth by $\Delta_L$) should be of order $10^{12}$ GeV. Clearly the presence of such a light triplet is going to affect unification of couplings.

The above remarks have the following implications:

• First and foremost is that $v_{B-L} \geq 10^{17}$ GeV which can happen if $SO(10)$ first breaks to $SU(5)$ which subsequently breaks to the standard model.

• Second is that maintaining gauge coupling unification would dictate that the $SU(2)_L$ triplet $\Delta_L$ be part of a complete $SU(5)$ 15 multiplet at the same scale.

We will explore under what conditions, these requirements are satisfied in our $SO(10)$ model. We must note that in deriving the above estimates for $v_{B-L}$ and $M_{\Delta_L}$, we have used the numerical values for the Yukawa couplings from the neutrino fit in Eq.(1). However, one could consider variations of type II seesaw $SO(10)$ models that contain a 120 multiplet where the value of $f_{33}$ is of order 0.1. In such a case, even a $v_{B-L} \simeq 2 \times 10^{16}$ GeV can lead to a triplet dominated type II seesaw, provided $M_{\Delta_L} \simeq 2 \times 10^{14}$ GeV. In this case also one needs both these conditions to be satisfied though at a somewhat milder level.

We now proceed to discuss how these conditions can be satisfied in the $SO(10)$ model that first breaks to nonminimal $SU(5)$ and then to the standard model.

### III. BREAKING $SO(10)$ TO STANDARD MODEL VIA $SU(5)$

We start with the minimal Higgs fields $H(10)$, $\Phi(210)$, $\Sigma(126)$ and $\Sigma(126)$ and write down the most general renormalizable super-potential:

$$W = \frac{m_{\Phi}}{2 \times 4!} \Phi^2 + \frac{m_{\Sigma}}{5!} \Sigma \Sigma + \frac{m_{H}}{2} H^2 + \frac{\lambda}{4!} \Phi^3 + \frac{\eta}{4!} \Phi \Sigma \Sigma + \frac{1}{4!} \Phi H (\alpha \Sigma + \alpha \Sigma)$$

We then extract the various $SU(5)$ submultiplets from each of the $SO(10)$ Higgs multiplets and rewrite the superpotential in terms of these fields. Extensive discussion of the decomposition of $SO(10)$ multiplets in terms of its subgroups as well as detailed analysis of the potential exists in the literature. We have calculated the $SU(5)$
decomposition of various SO(10) invariant couplings and use them in this paper. For this purpose note that

$$210 = 1_0 \oplus 5_{-8} \oplus \bar{5}_{+8} \oplus 10_4 \oplus \overline{10}_{-4} \oplus 24_0 \oplus 75_0 \oplus 40_{-4} \oplus 40_{+4}$$  \hspace{1cm} (10)$$

$$126 = 1_{-10} \oplus \bar{5}_{-2} \oplus 10_{-6} \oplus 10_{+6} \oplus 45_2 \oplus 50_{-2}$$  \hspace{1cm} (11)$$

In terms of the properly normalized SU(5) submultiplets we now rewrite first the bilinear terms and then the trilinear terms in the superpotential

$$L_B = m_H H_a H^a + m_\Phi \left\{ (\Phi^5)_a (\Phi^5)^a + \frac{1}{3!} (\Phi^{40})_{abc} (\Phi^{40})^{abc} \right\}$$  \hspace{1cm} (12)$$

$$+ \frac{1}{2} (\Phi^{10})_{ab} (\Phi^{10})^{ab} + \frac{1}{8} (\Phi^{24})_{ab} (\Phi^{24})^{ab} + \frac{1}{2} (\Phi^{10})_a (\Phi^{24})^a$$

$$+ m_\Sigma \left\{ \sigma_o \gamma_o + \frac{1}{4!} (\Sigma^{15})_{a}^{bcde} (\Sigma^{15})_{b}^{acde} + \frac{1}{2!} (\Sigma^{10})_{ab} (\Sigma^{10})^{ab} \right\}$$

$$+ \frac{1}{12} (\Sigma^{50})_{abc} (\Sigma^{50})^{abc} + \frac{1}{2} (\Sigma^{45})_{a}^{bc} (\Sigma^{45})_{b}^{ac} + (\Sigma^{5})_{a} (\Sigma^{5})^{a} \right\}$$

and the trilinear term become

$$L_T = \frac{\lambda}{\sqrt{10}} \Phi_o \left\{ 12 (\Phi^5)_a (\Phi^5)^a + 3 (\Phi^{10})_{ab} (\Phi^{10})^{ab} + (\Phi^{24})_a (\Phi^{24})^a - \frac{1}{2} (\Phi^{75})_{ab} (\Phi^{75})^{ab} \right\}$$  \hspace{1cm} (13)$$

$$+ \sqrt{6} \sigma_o H^a (\Phi^5)^a + \sqrt{3} \Phi_o H^a (\Sigma^5)^a + \alpha \sigma_o H_a (\Phi^5)^a + \alpha \sqrt{3} \Phi_o H_a (\Sigma^5)^a$$

$$+ \sqrt{6} \eta \sigma_o \left\{ (\Phi^5)_a (\Sigma^5)^a + \frac{1}{2} (\Phi^{10})_{ab} (\Sigma^{10})_{ab} \right\} + c.c.$$

$$+ \eta (\Sigma^{10})_{a}^{ab} (\Sigma^{10})_{b}^{ab} + \frac{1}{12} (\Sigma^{15})_{a}^{bcde} (\Sigma^{15})_{b}^{acde} - \frac{1}{3!} (\Sigma^{50})_{abc} (\Sigma^{50})^{abc} + 4 (\Sigma^{5})_{a} (\Sigma^{5})^{a} \right\}$$

$$+ \frac{2\lambda}{\sqrt{10}} \Phi^3_o + \eta \sqrt{10} \Phi_o \sigma_o \sigma_o$$

A. SYMMETRY BREAKING AND RELATIONS AMONG THE PARAMETERS

We can now discuss SO(10) breaking to SU(5). There are three SU(5) singlets: one in each of the 126 pair and one in 210. The SU(5) singlets in the 126 pair have nonzero B-L and therefore B-L breaking scale is same as the SO(10) scale. Since supersymmetry must remain unbroken all the way down to the weak scale, we set the F-terms to zero. These F conditions give the following constraints on the vacuum expectation values:

$$F_{\Phi_o} = m_\Phi \Phi_o + 6 \lambda \Phi_o^2 + \eta \sigma_o \sigma_o = 0$$  \hspace{1cm} (14)$$
\[ F_{\sigma_o} = \sigma_o (m_\Sigma + 10\eta \Phi_o) = 0 \]

where \( \Phi_o = \frac{\Phi}{\sqrt{10}} \). The solution that breaks B-L is

\[ \Phi_o = \frac{-m_\Sigma}{10\eta} \]

\[ \sigma_o \sigma_o = \frac{m_\Sigma}{10\eta^2} (m_\Phi - \frac{3\lambda m_\Sigma}{5\eta}) \]  

Note that with this minimal set of Higgs fields, \( \sigma_o \sigma_o \) has to be non-vanishing in order to get the standard model group below the GUT scale because the \( \sigma_o, \bar{\sigma}_o \) are the only singlets that break the local B-L.

**B. MASSES OF SU(5) SUB-MULTIPLETS**

From the Lagrangian found above we easily write down the masses of the various SU(5) submultiplets; we list those with no mixing in Table I.

<table>
<thead>
<tr>
<th>Table I</th>
</tr>

<tbody>
<tr>
<td>40</td>
</tr>
<tr>
<td>75</td>
</tr>
<tr>
<td>24</td>
</tr>
<tr>
<td>15</td>
</tr>
<tr>
<td>50</td>
</tr>
<tr>
<td>45</td>
</tr>
</tbody>
</table>

**Table caption:** This table gives the masses of the various SU(5) multiplets in the SO(10) multiplets of the minimal model.

The mass matrix for the SU(5) singlets in the basis \( (\Phi_0, \sigma_0, \bar{\sigma}_0) \) is found to be:

\[
\begin{pmatrix}
    m_\Phi + 12\lambda \Phi_o & \sqrt{10\eta} \sigma_o & \sqrt{10\eta} \bar{\sigma}_o \\
    \sqrt{10\eta} \sigma_o & 0 & 0 \\
    \sqrt{10\eta} \bar{\sigma}_o & 0 & 0
\end{pmatrix}
\]  

One of the combination of the singlets has zero mass and is the Goldstone Boson corresponding to the breaking of B-L. As can be seen from the above matrix, the corresponding
field is a linear combination of the fields $\sigma_o$ and $\sigma_o$. Taking this out, we find the $2 \times 2$ mass matrix to be:

$$
\begin{pmatrix}
 m_\Phi + 12 \lambda \Phi_o & \sqrt{10} \eta \sqrt{\sigma_o^2 + \sigma_o^2} \\
 \sqrt{10} \eta \sqrt{\sigma_o^2 + \sigma_o^2} & 0
\end{pmatrix}
$$

(17)

The mass eigenvalues are given by:

$$
m_{\text{singlet}} = \frac{m_\Phi + 12 \lambda \Phi_o \pm \sqrt{(m_\Phi + 12 \lambda \Phi_o)^2 + 40 \eta^2 (\sigma_o^2 + \sigma_o^2)}}{2}
$$

(18)

The mass matrix for the 10 is

$$
\begin{pmatrix}
 m_\Phi + 6 \lambda \Phi_o & \sqrt{6} \eta \sigma_o \\
 \sqrt{6} \eta \sigma_o & -6 \eta \Phi_o
\end{pmatrix}
$$

(19)

This mass matrix has a zero eigenvalue and the associated eigenstate field is the Goldstone boson corresponding to the breaking of SO(10) down to $SU(5) \times U(1)$. The massive combination has mass

$$
m_{10} = -\frac{\eta}{\Phi_o} (|\sigma_o \sigma_o| + 6 \Phi_o^2)
$$

(20)

The mass matrix for 5-plet Higgs in the basis of $\mathbf{5} = (H, \Phi, \Sigma)$ and $\overline{\mathbf{5}} = (H, \Phi, \Sigma)$ is

$$
\overline{\mathbf{5}} \begin{pmatrix}
 m_H & \alpha \sigma_o & \sqrt{6} \alpha \Phi_o \\
 \alpha \sigma_o & m_\Phi + 12 \lambda \Phi_o & \sqrt{6} \eta \sigma_o \\
 \sqrt{6} \alpha \Phi_o & \sqrt{6} \eta \sigma_o & -6 \eta \Phi_o
\end{pmatrix} \mathbf{5}
$$

(21)

IV. NECESSITY OF 54 HIGGS FIELD

It is clear that in the minimal model with 10, 126 pair and a 210 the masses of the $SU(5)$ submultiplets 15, 50 and 45 are proportional to the same parameter $m_\sigma$. Therefore if we want to have 15 Higgs fields at the sub-$SU(5)$ scale of $10^{13}$ GeV, in order to enforce the type II seesaw formula with the triplet vev dominating, then we would have to have also the 45 pair and the 50 pair at nearly the same scale. This however will affect the evolution of gauge couplings very drastically. We therefore need a way to split only the 15 dim. field without affecting the other fields. As we show below, this is precisely what happens if we add to the model an additional 54 dimensional Higgs field. The main reason for this is that the 54 Higgs field contains an additional $SU(5)$ 15 Higgs field.
In the presence of the 54 Higgs field (denoted by $S$), the superpotential of Eq. (9) has the following additional terms:

$$ W_{54} = \frac{m_{15}}{4} S_{ab} S_{ab} + \frac{\lambda_1}{3!} S_{ab} S_{bc} S_{ca} + \frac{\lambda_2}{2} S_{ab} H_a H_b $$

$$ + \frac{\lambda_3}{2 \times 4!} S_{ab} \Sigma_{acdef} \Sigma_{bcdef} + \frac{\lambda_3}{2 \times 4!} S_{ab} \Sigma_{acdef} \Sigma_{bcdef} + \frac{\rho}{12} S_{ab} \Phi_{acde} \Phi_{bcde} \quad (22) $$

Note that $54 = 15_4 + 15_{-4} + 24_0$ under SU(5). Therefore when $\sigma_o = \sigma_o = v_{B-L}$, the 15 multiplets have a $2 \times 2$ mass matrix of the form:

$$ \begin{pmatrix} \frac{4}{5} m_\Sigma & \sqrt{2} \lambda_3 \sigma_o \\ \sqrt{2} \lambda_3 \sigma_o & m_{15} \end{pmatrix} \quad (23) $$

Similarly the 24 in 210 and in 54 mix and we have the following mass matrix for the 24 Higgses:

$$ \begin{pmatrix} m_\Phi + 2 \lambda \Phi_o \sqrt{6} \rho \Phi_o \\ \sqrt{6} \rho \Phi_o \end{pmatrix} \quad (24) $$

There is no effect on the 45 and 50 Higgs masses. We can now fine tune the 15 mass matrix to get one $15+\overline{15}$ lower mass (at $10^{13}$ GeV), while keeping the other pair at the SO(10) scale. We could not have done this without the 54 field. Furthermore, we fine tune the parameters in 24 mass matrix to keep one 24 at the SU(5) scale. Since the parameters in the 24 and 15 mass matrices are different, the two fine tunings can be done independently.

We thus conclude that in the minimal SO(10) model for the triplet term to dominate type II seesaw formula, the minimal Higgs set required are: 10, 126-pair, 210 and 54 dimensional.

We believe this result is interesting with important implications for SO(10) model building.

V. NEW MINIMAL MODEL

As already noted, the numerical analysis of neutrino sector indicates that $f_{33} \sim 10^{-3}$ if the mixing angle $\alpha_{2}^u$ is of order 1 and the mass of the triplet Higgs field has to be order of $10^{12}$ GeV in order for the triplet term in type II seesaw to dominate. However, if the mixing angle can be reduced, $f$ will increase and the the mass of the triplet can be higher. For
example, if the mixing angle is reduced by a factor of $10^{-4}$, $f_{33}$ will increase by the same factor and the triplet mass just needs to be $10^{16}$ GeV. While no fine tuning in Higgs $15$ mass is needed in this case, one needs a fine tuning in the values of the Higgs mixing parameter that will allow an increase in the value of $f_{33}$. This is due to the fact that the fit that requires $r_1 \sim 0.014$, $r_2 \sim 0.15$ and $\tan \beta = 10$, we need $\alpha^d_2 \sim \alpha^u_2 \sim 0.0001$ and $\alpha^d_1 \sim 0.1$ in order to get the required triplet mass up to GUT scale.

Furthermore, making the triplet of $15$ light by fine tuning always leaves other components heavy. In this case the coupling unification is destroyed.

Here we show in the model with $54$ Higgs the relative lightness of $15$ is achieved without bringing down any other unwanted multiplet below the SO(10) scale. The symmetry breaking scheme is two step type as before. First, SO(10) is broken at the scale of $10^{18}$ GeV down to SU(5) and then, to Standard model at the GUT scale ($2 \times 10^{16}$ GeV).

A. SUPERSYMMETRIC VACUUM

The equations of $F_i = 0$ with non-vanishing $v_{B-L}$ are

$$m_\phi S_- + 6\lambda S^2_o + \eta \sigma o \sigma_o + 2\rho S S_- = 0$$

$$m_\phi S_+ + 2\lambda (S^2_+ + 2S^2_o) + \eta \sigma_o \sigma_o - \frac{4}{3} \rho S S_+ = 0$$

$$m_\phi S_o + 2\lambda (S_- + 2S_+) S_o + \eta \sigma_o \sigma_o + \frac{1}{3} \rho S S_o = 0$$

$$m_\Sigma + \eta (S_- + 3S_+ + 6S_o) = 0$$

$$\frac{5}{6} m_{15} S + \frac{5}{36} \lambda_1 S^2 + \rho (S^2_o + S^2_- - 2S^2_+) = 0$$

where $S$ is the vev of the $24$ in $S$ and $S_{\pm,o}$ are the linear combinations of the vev of $24$, $75$ and $1$ in $\Phi$. They can be written explicitly as

$$S_+ = \frac{1}{3} < 75 > - \frac{2}{9} < 24 > + < 1 >$$

$$S_- = < 75 > + \frac{1}{3} < 24 > + < 1 >$$

$$S_o = - \frac{1}{3} < 75 > + \frac{1}{18} < 24 > + < 1 >$$

Note that $< 1 > = \tilde{\Phi}_o$ breaks the SO(10) down to SU(5) and other components break the SU(5) down to the MSSM. In order for the two-step symmetry breaking to happen, we
need to have \( S_i = \bar{\Phi}_o + m_{\Phi} s_i \) and \( S = \frac{m_{\Phi}}{\rho x} s \) \((x = \frac{\Phi_o}{m_{\Phi}})\) with all \( s_i \) and \( s \) much less than 1 (they are of order \( 10^{-2} \) in our scheme). The equations up to leading order become

\[
x + 6\lambda x^2 + \eta \frac{\sigma_o \sigma_o}{m_{\Phi}^2} + s_+ + 12\lambda s_o x + 2s = 0
\]
\( (27) \)

\[
s_+ - s_- + 4\lambda x(s_+ - s_o) - \frac{10}{3}s = 0
\]
\[
s_o - s_- + 2\lambda x(s_- + 2s_+ - 3s_o) - \frac{5}{3}s = 0
\]
\[
s_- + 3s_+ + 6s_o = 0
\]
\[
\frac{5m}{6}s + 2(S_o + S_- - 2S_+) = 0
\]

where \( m = \frac{m_{\Phi} - \frac{1}{\rho x}}{m_{\Phi}} \).

The first equation in \((27)\) can be satisfied by solving \( \sigma_o \sigma_o \). In order to have non-vanishing solution of \( s \)'s, we require the condition

\[
\text{Det} \left( \begin{array}{cccc}
1 + 4\lambda x & -4\lambda x & -1 & -4 \\
4\lambda x & 1 - 6\lambda x & -1 + 2\lambda x & -2 \\
3 & 6 & 1 & 0 \\
-4 & 2 & 2 & m
\end{array} \right) = 0
\]

\( (28) \)

This gives \( x\lambda = \frac{1}{4} \) or \( m = \frac{12}{1 + 2\lambda x} \). In the first case, the 75 Higgs will be light and has huge contribution to the RG running above the SU(5) scale. This will bring the coupling constant to the strong regime below the required 10^{18} GeV. We will exclude this and set \( x\lambda \neq -\frac{1}{2}, \frac{1}{4} \) from now on. The solution is given by

\[
\begin{pmatrix}
  s_+ \\
  s_o \\
  s_-
\end{pmatrix} = \frac{s}{3(1 + 2\lambda x)} \begin{pmatrix}
  4 \\
  -1 \\
  -6
\end{pmatrix}
\]

\( (29) \)

Compared with the explicit forms of \( s_{\pm,o} \), this solution corresponds to \( <75> = 0 \) and \( \frac{<\Phi_o^{24}>}{<S^{24}>} = \frac{-6}{1 + 2\lambda x} \) as a result of our choice to keep the 75 heavy.
B. effective SU(5) superpotential

At the SU(5) level, the effective superpotential that emerges from the SO(10) theory can be written as:

\[
W_{SU(5)} = h_d T \bar{F}_5 + f_d T \bar{F}_{45} + h_u T T F_5 + f_u T T F'_{5} \\
+ h_u F \bar{F}_{15} + h_D F \bar{F}_5 N + W_{Higgs}
\]

where the Higgs part of the superpotential \( W_{Higgs} \) is given by

\[
W_{Higgs} = \sum_a M_a \chi_a \bar{\chi}_a + W_{Tr}
\]

with \( \chi_a \) going over all the multiplets. We only give the trilinear terms of the form \((24)(15)(\bar{15})\) that will contribute a mass terms to the \( 15 \) when the \( 24 \) get a vev. We found

\[
W_{Tr} = - \sqrt{3} \eta \Phi_a ^b \sum_{bc} \Sigma_{bc} \lambda_{ac} + \lambda_1 S_a ^b S_{bc} S^{ac} + \cdots
\]

With appropriate fine tuning, we can reduce the nonminimal SU(5) group down to the MSSM where the Higgs fields are linear combinations of the standard model doublets in \( 5 \) and \( 45 \) fields.

C. MASS OF 15

Below the SO(10) scale \( M_{10} \), the mass of \( 15 \) is given in Eq. \[34\]

\[
M_{15} = \left( \begin{array}{c}
\frac{4}{5} m_{\Sigma} \\
\frac{1}{\sqrt{2} \lambda_3 \bar{\sigma}_o}
\end{array} \right) \left( \begin{array}{c}
\sqrt{2} \lambda_3 \sigma_o \\
\lambda_{15}
\end{array} \right)
\]

In order to have one light \( 15 \), we require \( \frac{4}{5} m_{\Sigma} m_{15} = 2 \lambda_3 \bar{\lambda}_3 \sigma_o \bar{\sigma}_o \). The two \( 15 \) can then be written in term of the light and heavy \( 15, 15_L \) and \( 15_H \). In term of the light field \( 15_L \), Eq.\[34\] become

\[
W_{Tr} = (8 m_3^2 \lambda_1 S^{24} - 25 \sqrt{3} \eta \lambda_3 \bar{\lambda}_3 \sigma_o \bar{\sigma}_o \Phi^{24}) \bar{15}_L 15_L + \cdots
\]

where \( \cdots \) stand for terms involve heavy particle. This will give a mass of order \( 10^{16} \) GeV to the light \( 15 \) and will destabilize the whole multiplet at the scale of \( 10^{14} \) GeV. To stabilize the \( 15 \), we set this term to zero and that require
\[ 8m_{15}^2 \lambda_1 < S^{24} >= 25\sqrt{3} \eta \lambda_3 \overline{\sigma}_o < \Phi^{24} > \]  

(36)

The corrections of the 15 mass thus come from the higher dimensional operators, which in general have contribution of order \[ \langle \frac{\Phi^{24}}{M_{10}} \rangle \sim 10^{14} \text{ GeV}. \] The splitting between different multiplets in 15 are at most of this order and the effect on the unification of coupling is like the small threshold effect.

D. MASS OF 5

In our scenario, 45 is heavy and so its contribution to the physical Higgs doublet comes from the integrating out the 45. The mixing angle \( \alpha^d_2 \) is therefore small (\( \sim 10^{-2} \)). We now analyze the physical Higgs mass from 5’s in the approximation of SU(5) symmetry. The mass matrix is given in Eq. (21). Again, the determinant of the matrix has to be zero. That gives

\[ \frac{\lambda}{\eta} = \frac{2\alpha \overline{\alpha} \sigma_o \overline{\sigma}_o}{\eta m_H \Phi_o + \alpha \overline{\alpha} \Phi_o^2} \]  

(37)

The small mixing of \( \Sigma_5 \) (\( \alpha^d_2 \sim 10^{-2} \)) require

\[ \frac{2\sqrt{6} \overline{\alpha} \eta \overline{\Phi}}{\alpha \overline{\alpha} \Phi_o - \eta m_H} = 100 \]  

(38)

and \( \alpha^d_1 \sim 0.1 \) require

\[ \frac{\alpha}{\alpha} = 10^3 \]  

(39)

or

\[ \frac{\overline{\alpha} \Phi_o}{\eta \sigma_o} = -10 \]  

(40)

To summarize, we collect all conditions from the arguments above.

\[ \sigma_o \overline{\sigma}_o = -(x + 6 \lambda x^2 + s_+ + 12 \lambda s_o x + 2 s) \frac{m^2}{\eta} \]  

(41)

\[ m = \frac{12}{1 + 2 \lambda x} \]  

(42)
When these conditions are all satisfied, we have the required triplet dominated type-II seesaw. Because \( m, \lambda_1 \) and \( \chi \) are free parameters, equation (42), (44) and (45) can be satisfied by assigning the correct value to these three parameters. Equation (47) can be satisfied by tuning the denominator. We simply set the denominator of equation (47) to zero and find that

\[
\frac{\alpha\phi_0}{\eta\sigma_0} = -10
\]

where we have simplified equation (41) by including only the leading order terms. Note that \( x = \frac{\phi_0}{m_5} \). We found from the equations above that \( \lambda x = \frac{1}{7} \). If \( m_H \sim m_\phi \), we have also found the relations \( \frac{\phi_0}{\sigma_0} = \frac{7}{100} \) and \( \frac{\alpha}{\sqrt{\lambda x}} = 10 \). There are enough free parameters in the model to allow the above equations to be satisfied simultaneously. In this model we have \( f_{33} \sim 0.1 \), \( v_{B-L} = 10^{18} \) GeV, the triplet mass \( M_T \sim 10^{14} \) GeV and the GUT scale remains at \( 2 \times 10^{16} \) GeV.

One of the obvious concerns one may have with a 15-Higgs field around a mass of \( 10^{14} \) GeV is its contribution to proton decay. As has been discussed very early on in the study of SU(5) theories, 15 Higgs field cannot contribute to proton decay in the limit of exact \( SU(2)_L \). Therefore, typical strength of proton decay amplitude arising from the exchange of 15 Higgs is \( \sim \frac{\nu_{\alpha k} h_{\alpha} h_{d} m_{15} \sigma_0}{4\pi m_\phi^2} \sim h_{\alpha} h_{d} 10^{-32} \) GeV\(^{-2} \). This is far below the present experimental limits on this strength.
VI. GAUGE UNIFICATION AND SO(10) SCALE

Given the above multiplet structure, we can now evaluate the SO(10) unification scale. Since a viable type II theory requires that SO(10) breaking be at least a factor of 5 bigger than the SU(5) scale, we need to see if the gauge coupling remains perturbative (i.e. $\alpha_U \leq 1$) until the SO(10) scale $M_{10}$. For this purpose let us assume that the theory below the SU(5) scale is MSSM as a starting point. Taking the contributions of the various new Higgs fields above the SU(5) scale $M_5$, we find that

$$\alpha_{10}^{-1} = \alpha_5^{-1} - \frac{b_5}{2\pi} \ln \left( \frac{M_{10}}{M_5} \right)$$

(50)

where $b_5$ is the contribution of the supermultiplets with masses between the SU(5) and the SO(10) scale. In order to determine $\alpha_{10}$, we need the value of $\alpha_5$ as well as the coefficient $b_5$. The former will be different from the canonical MSSM value since now there is a full $15$-dim. multiplet below the SU(5) scale $M_5$. Let us proceed to calculate this.

The running of the standard model gauge couplings from the electroweak scale to the SU(5) unification scale can be written as

$$\alpha_i^{-1}(m_Z) = \alpha_i^{(0)} - \frac{b_i}{2\pi} \ln \left( \frac{M_5}{M_Z} \right) + \delta_i$$

(51)

where $\alpha_{i=1,2,3}$ are the properly normalized $U(1)$, SU(2) and SU(3) gauge couplings, $\alpha_5$ and $M_5$ are the SU(5) gauge coupling and unification scale. The last term in (51) is the correction due to light multiplets (i.e with mass smaller than $M_5$). In our model it corresponds to the $15 + \bar{15}$ chiral superfields responsible for the type II see-saw and is given by

$$\delta_i = \delta b_i \ln \left( \frac{M_5}{M_{15}} \right)$$

(52)

where

$$\vec{\delta b} = (7, 7, 7)$$

(53)

Now it is straightforward to show that

$$\alpha_5 = \frac{\alpha_5^{(0)}}{1 + \alpha_5^{(0)} \Delta_5}$$

(54)

$\alpha_5^{(0)}$ is the value of the SU(5) gauge coupling with the MSSM spectrum, and $\Delta_5$ is given by

$$\Delta_5 = -\frac{1}{56\pi} \left[ 5(\delta_2 - \delta_1) + 28\delta_2 \right] = -\frac{1}{2\pi} \delta_2$$

(55)
With $M_{15} \sim 10^{14}$ GeV the gauge unification coupling increases by $\sim 15\%$ which amounts to an increase of about $30\%$ in the proton decay life time via the dimension 6 operators. The $SU(5)$ unification scale and the value of $\alpha_{\text{strong}}(m_Z)$ are unaffected by the extra light complete multiplet. In Fig. 1, we show the coupling constant evolution in the case with the $15$ mass at $10^{13}$ GeV.

**Table Caption:** The $SU(5)$ gauge coupling and proton decay with the 15 – plet mass $M_{15} = \{10^{11}, 10^{12}, 10^{13}, 10^{14}\}$ GeV
Using this value of $\alpha_5$ we can evaluate $\alpha_{10}$ and check whether it is perturbative at $M_{10}$. With one pair of $\{15, 5\}$ and one 24 we find $M_{10} \simeq 5.5 \times 10^{18}$ for $\alpha_{10} \simeq 1$. If we assume two 24 and three pairs of 5 below the $SO(10)$ scale we get $M_{10} \simeq 10^{18}$ GeV. Either of these values are sufficient to make the second term in the seesaw formula small and make the triplet term dominate the neutrino mass.

VII. CONCLUSION

We have given a thorough discussion of the conditions under which the triplet term in type II seesaw dominates the neutrino mass formula in a class of $SO(10)$ models with 126 that have been shown to lead to successful predictions of neutrino masses and mixings. This turns out to impose nontrivial constraints on the nature of symmetry breaking and Higgs structure of the model. For instance, we find that the minimal Higgs structure consistent with requirements of gauge coupling unification and triplet dominated type II seesaw is a combination of 210 and 54 multiplets in addition to the multiplets 10 and the 126 pair required for fermion masses. We give a detailed analysis of the Higgs potential, the resulting mass pattern of Higgs fields as well as the gauge coupling evolution in these models. We find that the $SO(10)$ must first break to a non-minimal SU(5) at a scale of about $10^{18}$ GeV with SU(5) subsequently breaking down to MSSM at $2 \times 10^{16}$ GeV. A complete SU(5) 15-plet must be around a $10^{13}$ GeV scale to lead to both a triplet dominated type II seesaw and gauge coupling unification. A low scale 15 does not lead to any new rapid proton decay modes. It can lead to $\Delta B = 2$ transitions such as neutron-anti-neutron oscillation but the rate for this process in this model is too small to be observable. We wish to emphasize that this symmetry breaking pattern leaves our considerations for proton decay unchanged. It is interesting that the triplet mass being of the order $10^{13}$ GeV might generate a baryon asymmetry through its lepton violating interactions.
